# What is Model Debugging?

- Model debugging is an emergent discipline focused on discovering and remediating errors in the internal mechanisms and outputs of machine learning models.\*
- Model debugging attempts to test machine learning models like software (because the models are software).
- Model debugging is similar to model validation and regression diagnostics, but for machine learning models.
- Model debugging **promotes trust directly and enhances interpretability as a side-effect.**

---

\* See <https://debug-ml-iclr2019.github.io/> for numerous examples of model debugging approaches.

# Why Debug?

**Government's Use of Algorithm Serves Up False Fraud Charges**

Using a flawed automated system, Michigan's attorney general charged thousands with wrongfully fraud and took millions from them.

**When a Computer Program Keeps You in Jail**

By Rebecca Weller

**A.C.L.U. Accuses Clearview AI of Privacy 'Nightmare Scenario'**

The facial recognition start-up violated the privacy of Illinois residents by collecting their images without their consent, the civil liberties group says in a new lawsuit.

**Self-Driving Uber Car Kills Pedestrian in Arizona, Where Robots Roam**

**Access Denied: Faulty Automated Background Checks Freeze Out Renters**

Microsoft's robot editor confuses mixed-race Little Mix singers

Fire's plan to reduce editorials with AI backfires after wrong image of Melania is published

**Instagram blames GDPR for failure to tackle rampant self-harm and eating-disorder images**

Exclusive: Telegraph investigation found Instagram's algorithms push dangerous content almost two years after it promised to crack down

By Lauren Brinkley, THE TELEGRAPH REPORTER, LONDON, AND CLAUDIO BONAGURA, THE TELEGRAPH REPORTER, NEW YORK CITY

**Leaving Cert: Why the Government deserves an F for algorithms**

Net results: Ireland's exam has a significant – and often negative – impact on all our lives

**Regulators probe racial bias with UnitedHealth algorithm**

Regulators say racial bias in algorithm leads to poorer care for black patients; UnitedHealth defends product.

By Christopher Grounds, STAR TRIBUNE

**Tiny Changes Let False Claims About COVID-19, Voting Evade Facebook Fact Checks**

October 9, 2020 - 6:01 AM ET

**Allstate's Algorithm Sucks List: How Allstate's Secret Auto Insurance Algorithm Squeezes Big Spenders**

UK passport photo checker shows bias against dark-skinned women

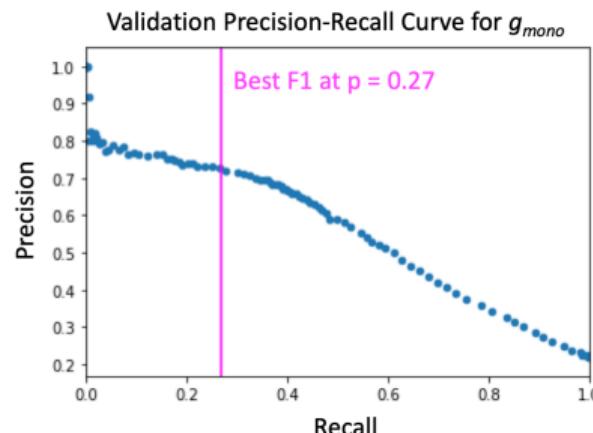

By Morgan Abrahams

**AI incidents:** The AI Incident Database contains over 2,000 incident reports.†

† See <https://incidentdatabase.ai/> to access the database.

# Why Debug?

- Constrained, monotonic GBM probability of default (PD) classifier,  $g_{mono}$ .
- Grid search over hundreds of models.
- Best model selected by validation-based early stopping.
- Seemingly well-regularized (row and column sampling, explicit specification of L1 and L2 penalties).
- No evidence of over- or under-fitting.
- Better validation logloss than benchmark GLM.
- Decision threshold selected by maximization of F1 statistic.
- BUT traditional assessment can be inadequate!**

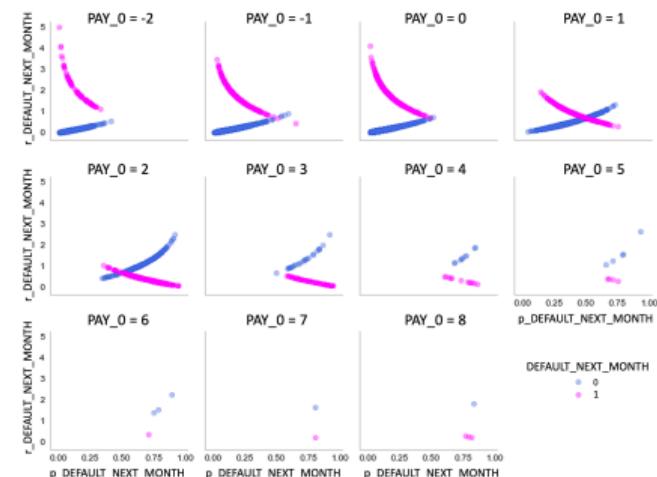

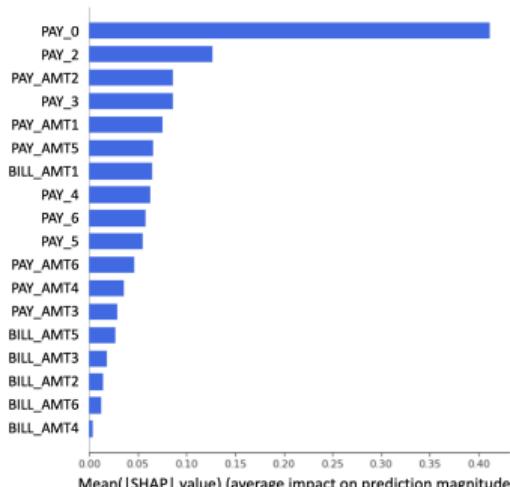

Validation Confusion Matrix at Threshold:

	Actual: 1	Actual: 0
Predicted: 1	1159	827
Predicted: 0	1064	6004

# Why Debug?

Machine learning models can be **unnecessary**.

**gmono** PD classifier over-emphasizes the most important feature, a customer's most recent repayment status, PAY\_0.

**gmono** also struggles to predict default for favorable statuses,  $-2 \leq \text{PAY}_0 < 2$ , and often cannot predict on-time payment when recent payments are late,  $\text{PAY}_0 \geq 2$ .

# Why Debug?

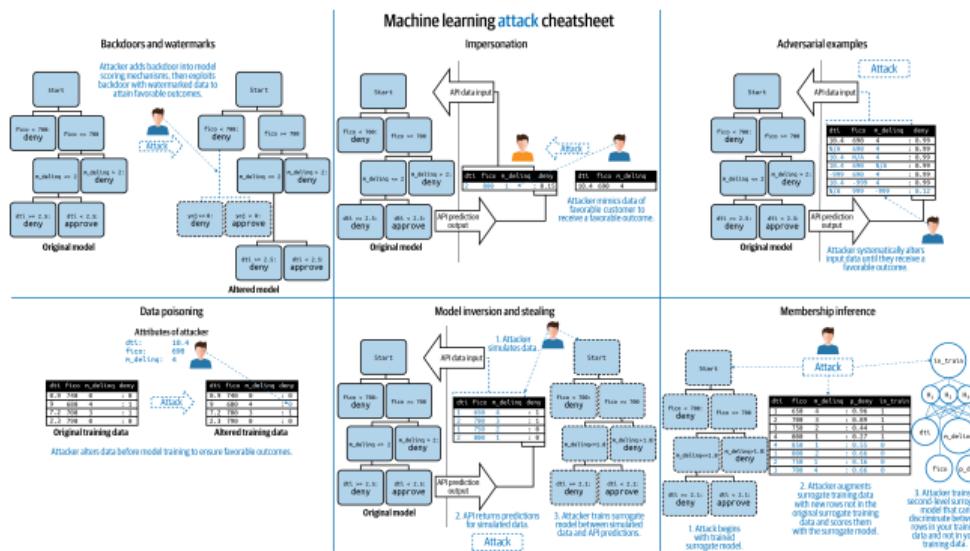

Machine learning models can perpetuate **sociological biases** [1].

<b>Adverse Impact Disparity</b>	<b>Accuracy Disparity</b>		<b>True Positive Rate Disparity</b>		
			<b>Precision Disparity</b>	<b>Specificity Disparity</b>	
<b>single</b>	0.885	1.029	0.988	1.008	1.025
<b>divorced</b>	1.014	0.932	0.809	0.806	0.958
<b>other</b>	0.262	1.123	0.62	1.854	1.169

Group disparity metrics are out-of-range for  $g_{mono}$  across different marital statuses.

# Why Debug?

Machine learning models can have **security vulnerabilities** [2], [6], [7].<sup>‡</sup>

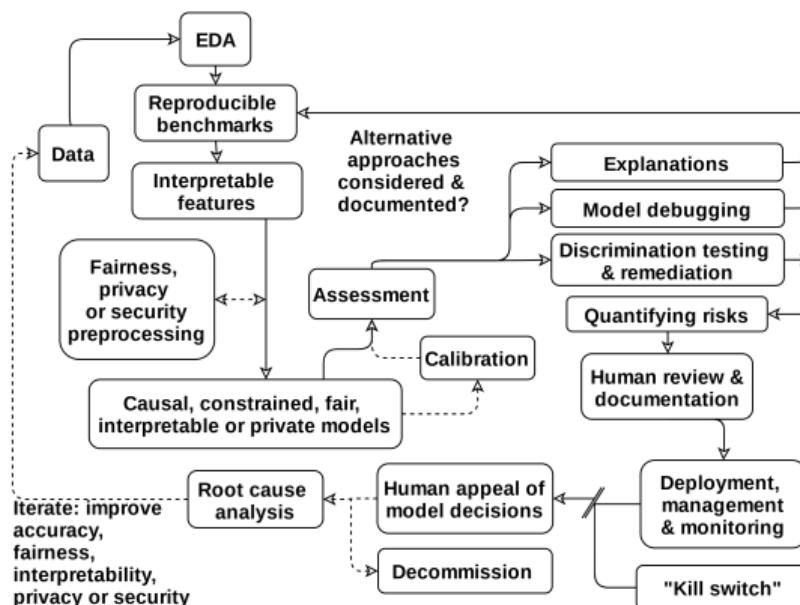

<sup>‡</sup>See <https://bit.ly/3jyYtzi> for full size image.

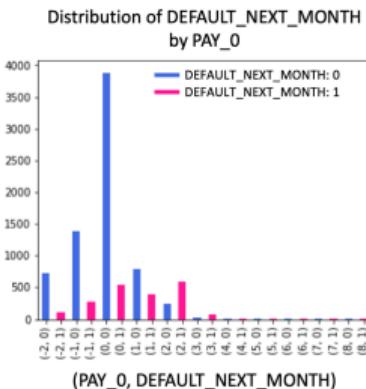

## How to Debug Models?

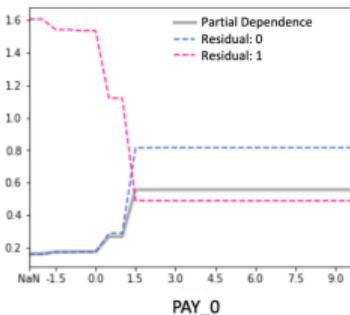

As part of a holistic, low-risk approach to machine learning [4].

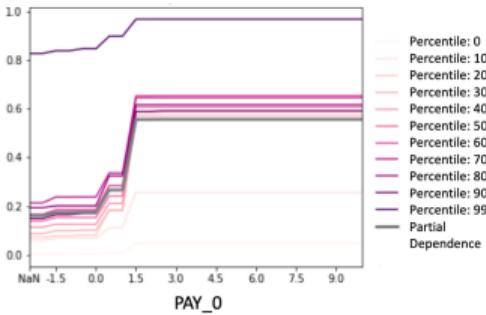

# Sensitivity Analysis: Partial Dependence and ICE

Out-of-Range Partial Dependence with  
Gloss Residuals

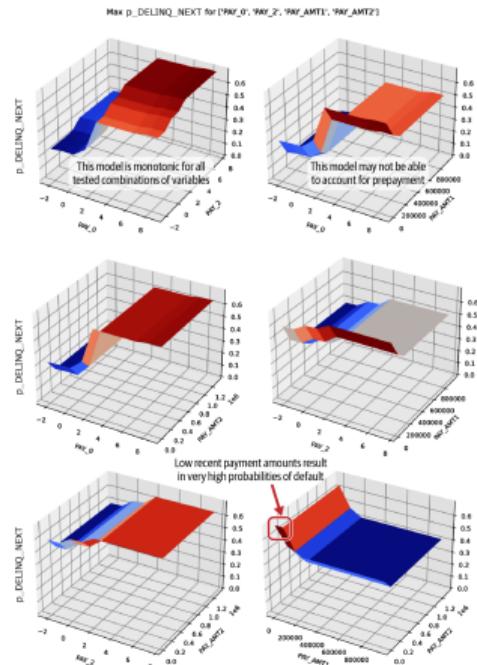

Out-of-Range Partial Dependence  
with ICE

- Training data is very sparse for  $PAY\_0 > 2$ .
- ICE curves indicate that partial dependence is likely trustworthy and empirically confirm monotonicity, but also expose adversarial attack vulnerabilities.
- Partial dependence and ICE indicate  $g_{mono}$  likely learned very little for  $PAY\_0 \geq 2$ .
- $PAY\_0 = \text{missing}$  gives lowest probability of default.

# Sensitivity Analysis: Search for Adversarial Examples

Adversary search confirms multiple avenues of attack and exposes a potential flaw in  $g_{\text{mono}}$  inductive logic: default is predicted for customer's who make payments above their credit limit. (Try heuristics, evolutionary learning or packages like [cleverhans](#) to generate adversarial examples.)

# Sensitivity Analysis: Robustness to Drift

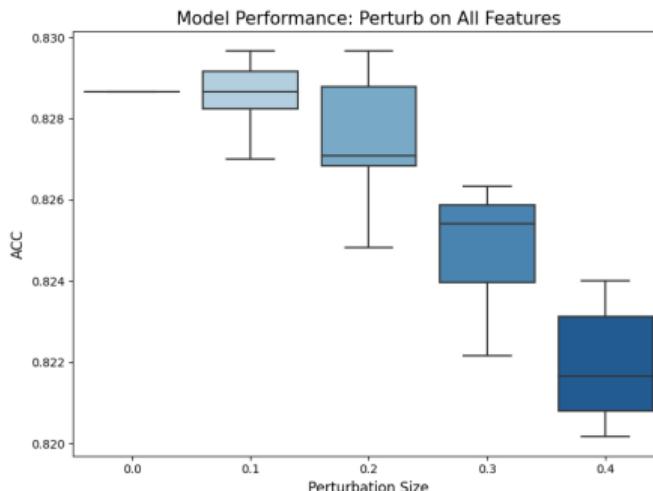

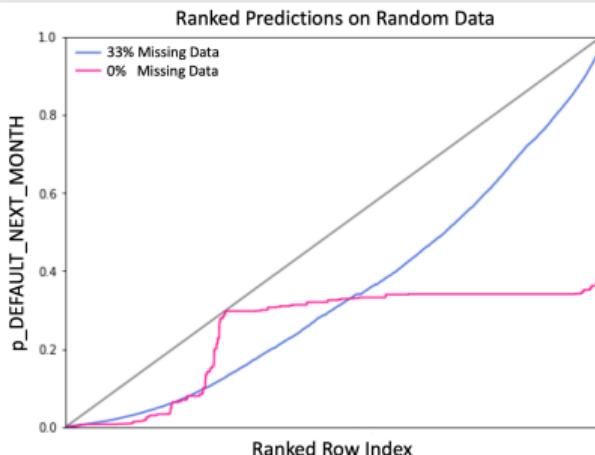

Figure:  $g_{mono}$  accuracy under feature perturbation.

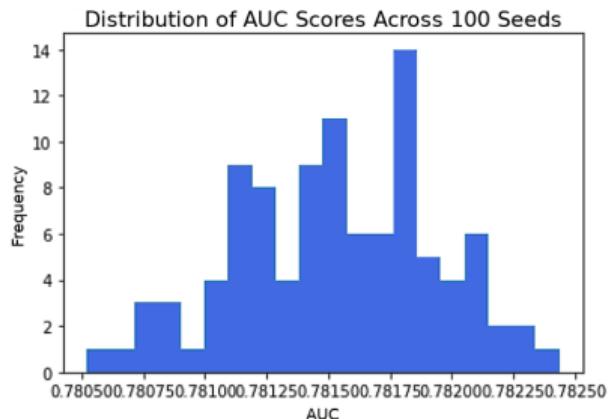

- Models must be robust to data drift once deployed.
- Simulation, perturbation, and statistics like population stability index (PSI),  $t$ , and Kolmogorov-Smirnov (K-S) can help assess robustness.
- Drift can also be measured on a feature-by-feature basis across data partitions.
- Likely due to monotonicity constraints  $g_{mono}$  holds up well to moderate data perturbation.

## Sensitivity Analysis: Random Attacks

- In general, random attacks are a viable method to identify software bugs in machine learning pipelines. **(Start here if you don't know where to start.)**
  - Random data can apparently elicit all probabilities  $\in [0, 1]$  from  $g_{\text{mono}}$ .
  - Around the decision threshold, lower probabilities can be attained simply by injecting missing values, yet another vulnerability to adversarial attack.
  - Chaos testing is a broader approach that can also elicit unexpected approaches from machine learning systems.

# Sensitivity Analysis: Underspecification

- Without domain-informed constraints ML models suffer from *underspecification* [3].
- Explicit tests for underspecification involve assessing model performance stability across perturbed computational hyperparameters: seeds, threads, number of GPUs, etc.
- Likely due to monotonicity constraints,  $g_{mono}$  performance appears stable across random seeds.

# Residual Analysis: Segmented Error Analysis

Error Metrics for PAY\_0

	Prevalence	Accuracy	True Positive Rate	Precision	Specificity	Negative Predicted Value	False Positive Rate	False Discovery Rate	False Negative Rate	False Omissions Rate
<b>PAY_0</b>										
-2	0.124	0.864	0.099	0.333	0.972	0.884	0.028	0.667	0.901	0.116
-1	0.168	0.816	0.206	0.406	0.939	0.854	0.061	0.594	0.794	0.146
0	0.121	0.867	0.107	0.341	0.972	0.888	0.028	0.659	0.893	0.112
1	0.325	0.491	0.903	0.381	0.292	0.862	0.708	0.619	0.097	0.138
2	0.709	0.709	1	0.709	0	0.5	1	0.291	0	0.5
3	0.748	0.748	1	0.748	0	0.5	1	0.252	0	0.5
4	0.571	0.571	1	0.571	0	0.5	1	0.429	0	0.5
5	0.444	0.444	1	0.444	0	0.5	1	0.556	0	0.5
6	0.25	0.25	1	0.25	0	0.5	1	0.75	0	0.5
7	0.5	0.5	1	0.5	0	0.5	1	0.5	0	0.5
8	0.75	0.75	1	0.75	0	0.5	1	0.25	0	0.5

Error Metrics for SEX

	SEX										
	Male	0.235	0.782	0.626	0.531	0.83	0.879	0.17	0.469	0.374	0.121
Male	0.235	0.782	0.626	0.531	0.83	0.879	0.17	0.469	0.374	0.121	
Female	0.209	0.797	0.552	0.514	0.862	0.879	0.138	0.486	0.448	0.121	

- Notable change in accuracy and error characteristics for PAY\_0  $\geq 2$ .
- For SEX, accuracy and error characteristics vary little across individuals represented in the training data. Bias mitigation should be confirmed by more involved bias testing.
- Overfitting, stability and other characteristics should also be analyzed by segment.
- Varying performance across segments can be an indication of underspecification.

# Residual Analysis: Plotting Residuals

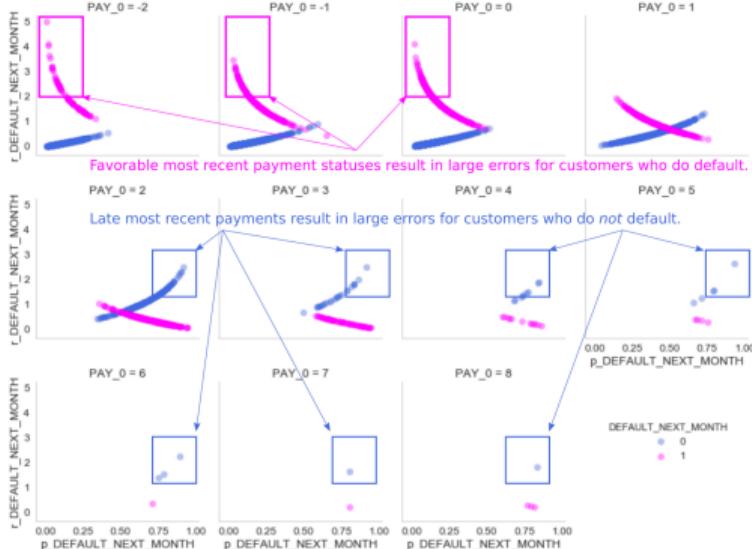

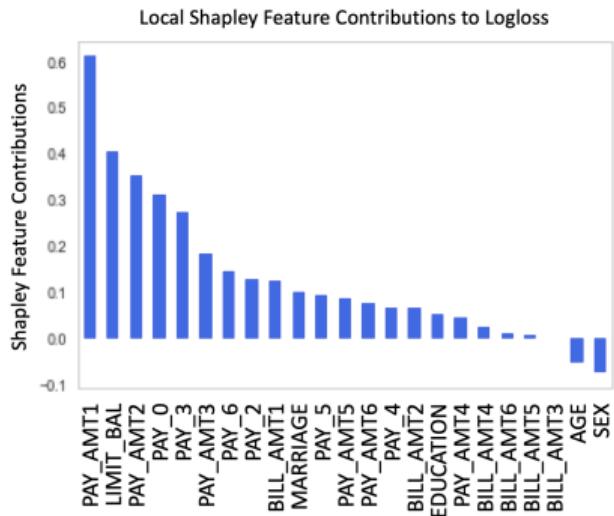

Figure: Residuals plotted by PAY\_0 reveal a serious problem with  $g_{\text{mono}}$ .

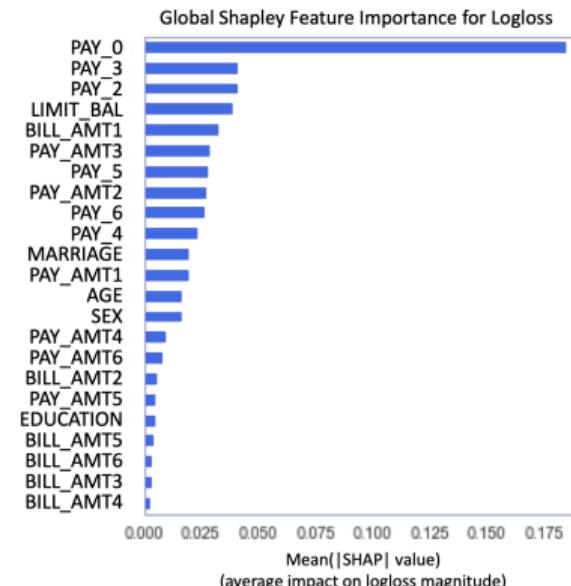

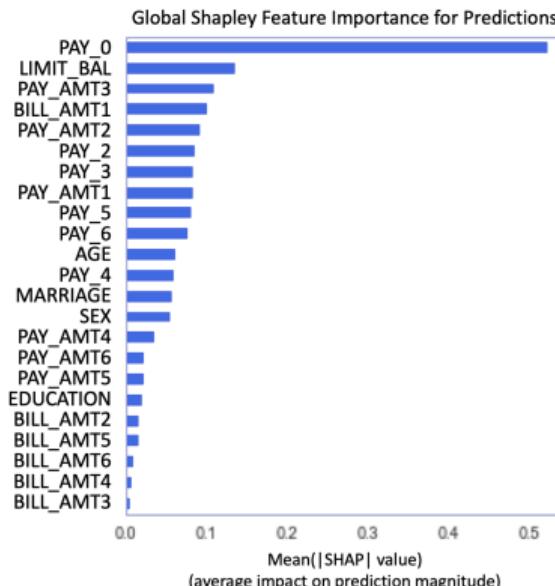

- Plotting residuals is a battle-tested model debugging technique.
- Residuals can be plotted using many approaches:
  - Overall, by feature (at left) or by segment
  - Traditional ( $\hat{y}^{(i)} - y^{(i)}$ )
  - Deviance or loss residuals (at left)
- Residuals can reveal serious issues and the underlying problems behind them.

## Residual Analysis: Local Contributions to Logloss

Exact, local feature contributions to logloss can be calculated, enabling ranking of features contributing to logloss residuals for **each prediction**. Shapley contributions to XGBoost logloss can be calculated using the **shap** package. This is a **time-consuming** calculation.

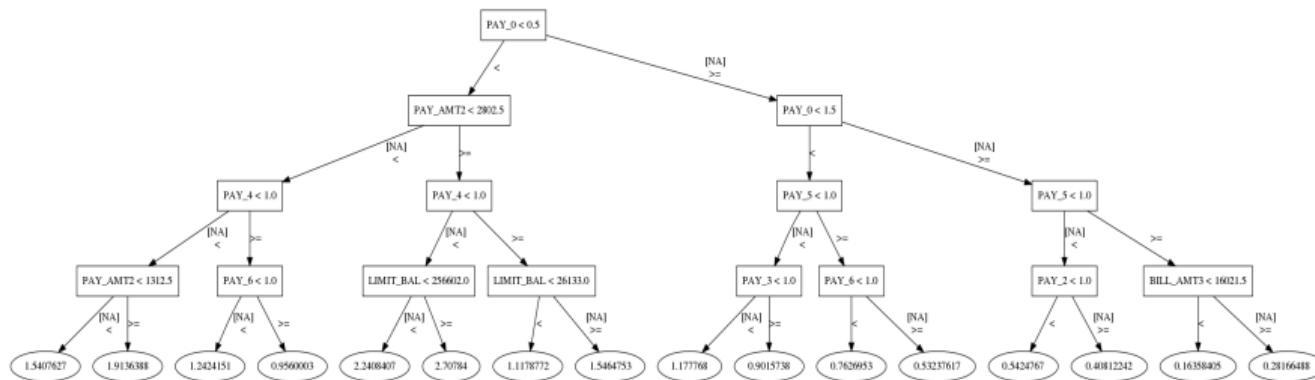

## Residual Analysis: Non-Robust Features

Globally important features PAY\_3 and PAY\_2 are more important, on average, to the loss than to the predictions.

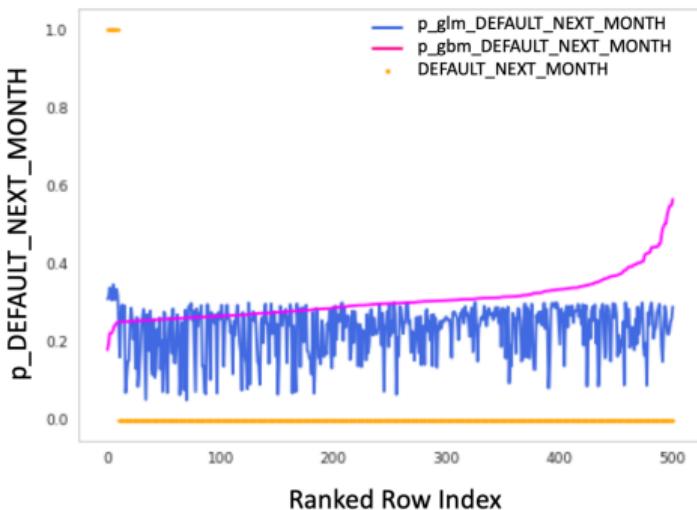

# Residual Analysis: Modeling Residuals

Decision tree model of  $g_{\text{mono}}$   $\text{DEFAULT\_NEXT\_MONTH} = 1$  logloss residuals with 3-fold CV MSE = 0.0070 and  $R^2 = 0.8871$ .

This tree encodes rules describing when  $g_{\text{mono}}$  is probably wrong.

## Benchmark Models: Compare to Linear Models

For a range of probabilities  $\in (\sim 0.2, \sim 0.6)$ ,  $g_{\text{mono}}$  displays exactly incorrect prediction behavior as compared to a benchmark GLM.

# Remediation: $g_{\text{mono}}$

- **Over-emphasis of PAY\_0:**
  - Engineer features for payment trends or stability.
  - Strong regularization or missing value injection during training or inference.
- **Sparsity of PAY\_0 > 2 training data:** Increase observation weights.
- **Payments  $\geq$  credit limit:** Inference-time model assertion [5].
- **Disparate impact:** Adversarial de-biasing [8] or model selection by minimal disparate impact.
- **Security vulnerabilities:** API throttling, authentication, real-time model monitoring.
- **Large logloss importance:** Evaluate dropping non-robust features.
- **Poor accuracy vs. benchmark GLM:** Blend  $g_{\text{mono}}$  and GLM for probabilities  $\in (\sim 0.2, \sim 0.6)$ .
- **Miscellaneous strategies:**
  - Local feature importance and decision tree rules can indicate additional inference-time model assertions, e.g., alternate treatment for locally non-robust features in known high-residual ranges of the learned response function.
  - Incorporate local feature contributions to logloss into training or inference processes.

## Remediation: General Strategies

## Technical:

- Calibration to past data
  - Data augmentation
  - Discrimination remediation
  - Experimental design
  - Interpretable models
  - Model or model artifact editing
  - Model assertions
  - Model monitoring
  - Monotonicity and interaction constraints
  - Strong regularization or missing value injection during training or inference

### Process:

- Appeal and override
  - Bug bounties
  - Demographic and professional diversity
  - Domain expertise
  - Incident response plans
  - Model risk management
    - Effective challenge and human review
  - Software quality assurance
  - Red-teaming
